# Non-linearity and Feature Expansion 

Ryan Miller

## Introduction

- Linear regressions and variants like logistic/softmax regression often lack the flexibility to learn certain patterns
- Sometimes this bias can be beneficial due to the corresponding reduction in variance, but in other situations it can be problematic
- This lecture introduces a few strategies to add flexibility to linear models (ie: reduce their bias)

## Example

Consider a simple application aiming to predict the resting metabolic rate of an individual using their bodyweight.

| weight_lbs | rate_kcal |
| ---: | ---: |
| 104.79 | 1079 |
| 106.68 | 1146 |
| 108.78 | 1115 |
| 110.46 | 1161 |
| 120.96 | 1325 |
| 128.94 | 1351 |

The raw data might consist of a single predictor and the outcome.

## Example

We might consider a simple linear model to represent this relationship:

How is it doing?

## Feature Expansion

To add flexibility to our linear model, we might expand our single predictor using polynomials:

| X1 | X2 | X3 | rate_kcal |
| ---: | ---: | ---: | ---: |
| 104.79 | 10980.94 | 1150693 | 1079 |
| 106.68 | 11380.62 | 1214085 | 1146 |
| 108.78 | 11833.09 | 1287203 | 1115 |
| 110.46 | 12201.41 | 1347768 | 1161 |
| 120.96 | 14631.32 | 1769805 | 1325 |
| 128.94 | 16625.52 | 2143695 | 1351 |

We're now using 3 columns to represent an individual's weight. They are: weight, weight squared, and weight cubed.

## Polynomial Expansion

A linear regression model fit to the expanded data is shown in red:

Did feature expansion improve the accuracy of our model on the training data?

## Bias-Variance Tradeoff

Because our second model estimated 3 weight parameters (and 1 bias) from the data, it has greater flexibility to represent small trends.

However, more flexibility is not always better, as the blue line above depicts and 8th degree polynomial expansion. What's wrong with this model?

## Discretization

A simple alternative to polynomial expansion is discretization:

| $(90.3,143]$ | $(143,196]$ | $(196,248]$ | $(248,301]$ | rate_kcal |
| ---: | ---: | ---: | ---: | ---: |
| 1 | 0 | 0 | 0 | 1079 |
| 1 | 0 | 0 | 0 | 1146 |
| 1 | 0 | 0 | 0 | 1115 |
| 1 | 0 | 0 | 0 | 1161 |
| 1 | 0 | 0 | 0 | 1325 |
| 1 | 0 | 0 | 0 | 1351 |

The idea is to split a numeric predictor in to categories and represent them using one-hot encoding.

## Discretization

The discretizing weight into 4 equally spaced bins yields the following model:

What are some strengths/weaknesses of this approach?

## Splines

Splines are an alternative without many of the negative aspects of polynomials and descretization:

| X1 | X2 | X3 | rate_kcal |
| ---: | ---: | ---: | ---: |
| 0.1768971 | 0.0128790 | 0.0003126 | 1079 |
| 0.1964682 | 0.0163547 | 0.0004538 | 1146 |
| 0.2172099 | 0.0206527 | 0.0006546 | 1115 |
| 0.2330538 | 0.0244103 | 0.0008523 | 1161 |
| 0.3175760 | 0.0537322 | 0.0030304 | 1325 |
| 0.3660471 | 0.0817907 | 0.0060919 | 1351 |

Basis splines, or "b-splines", use a basis matrix to represent piecewise polynomials that must connect at certain interior knots

## B-splines

Polynomials with degree $=1$ are just lines, the model below demonstrates a b-spline with 3 knots and degree $=1$ :

## B-splines

Higher degree splines ensure smoothness by requiring continuity of derivatives up to the order degree-1 (so quadratic splines require continuity of the first derivative, or slope at the location of the knot):

Degree $=2$ with 3 knots

## B-splines

The polynomial degree and number of knots can be used to manipulate the flexibility of $b$-splines:

The red line uses 3rd degree polynomial expansion, the green is a 3 rd degree basis spline expansion with knots at 150, 200, and 250 lbs, the blue reduces the degree to 2 and introduces additional knots at 1110 and 180 lbs .

## Closing Remarks

- Splines are useful when inspection of the relationship between a predictor and the outcome shows evidence of non-linearity
- The only scenario in which polynomials might be justified over splines are models intended to be explained to a non-technical audience
- Discretization is also generally less preferable to splines, but it might make sense in applications where clear thresholds are used
- For example, a grade of $70 \%$ might be substantially different from a grade of $69 \%$, but $71 \%$ or $72 \%$ might be roughly the same as a $70 \%$
